SIGNAL TRANSDUCTION

LZTR1 is a regulator of RAS ubiquitination and signaling

In genetic screens aimed at understanding drug resistance mechanisms in chronic myeloid leukemia cells, inactivation of the cullin 3 adapter protein-encoding leucine zipper-like transcription regulator 1 (*LZTR1*) gene led to enhanced mitogen-activated protein kinase (MAPK) pathway activity and reduced sensitivity to tyrosine kinase inhibitors. Knockdown of the *Drosophila LZTR1* ortholog *CG3711* resulted in a Ras-dependent gain-of-function phenotype. Endogenous human LZTR1 associates with the main RAS isoforms. Inactivation of *LZTR1* led to decreased ubiquitination and enhanced plasma membrane localization of endogenous KRAS (V-Ki-ras2 Kirsten rat sarcoma viral oncogene homolog). We propose that LZTR1 acts as a conserved regulator of RAS ubiquitination and MAPK pathway activation. Because *LZTR1* disease mutations failed to revert loss-of-function phenotypes, our findings provide a molecular rationale for *LZTR1* involvement in a variety of inherited and acquired human disorders.

hronic myeloid leukemia (CML) is characterized by the expression of the constitutively active oncogenic tyrosine kinase fusion BCR-ABL (1). The proliferation and survival of BCR-ABL⁺ CML cells depends on the activation state of key cellular signaling networks, including the mitogen-activated protein kinase (MAPK) pathway (1). The development of the tyrosine kinase inhibitor (TKI) imatinib has provided a successful targeted therapeutic, however limited by the development of resistance (2).

Genetic screens in the near-haploid human CML cell line KBM-7 allow unbiased identification of candidate genes that affect inhibitor resistance (3). We performed comprehensive haploid genetic screening with six TKIs in clinical use or under evaluation (fig. SIA). Retroviral genetrap mutagenized cells were exposed to the TKIs at concentrations corresponding to half maximal inhibitory concentration (IC^{50}) to IC^{70} dosage (fig. S1B), resistant cell populations were collected after selection, and genomic gene-trap insertions were identified by means of deep sequencing. Each screen resulted in enrichment of disruptive insertions in 5 to 18 different genes (Fig. 1A; figs. S1, C to G, and S2A; and table S1). We identified a recurrent set (\geq 4 screens) of six genes (*NF1, WT1, PTPN1, PTPN12, LZTR1*, and *BAP1*; "TOP6" set) (Fig. 1B) with overrepresentation of disruptive genomic gene-trap integrations, strongly indicating a selective advantage upon drug treatment (fig. S2B).

We used a lentiviral CRISPR/Cas9 multicolor competition assay (MCA)-based coculture system to evaluate gene-mediated drug-resistance effects. SpCas9-expressing KBM-7 (KBM-7^{Cas9}) cells were infected with lentiviral single-guide RNA (sgRNA) vectors that coexpress reporter fluorophores, which enabled the tracing of knockout and control cell populations by means of flow cytometry in the same well (fig. S3A). Mixed sgRen (targeting Renilla luciferase) control cell populations that express fluorescent proteins (GFP⁺ or mCherry⁺) did not show any preferential outgrowth of resistant cells upon 14 days of TKI treatment (Fig. 1C and fig. S3H). By contrast, KBM-7^{Cas9} GFP⁺ cells harboring sgRNAs that target the TOP6 genes showed a decreased amount of cognate protein (fig. S3, B to G) and demonstrated enhanced cell survival and outgrowth in the presence of imatinib (Fig. 1C) and rebastinib (fig. S3H). Thus, we functionally validated the TOP6 genes as important for drug action in BCR-ABL⁺ CML cells.

Although *NF1*, *PTPN1*, and *PTPN12* share the ability to modulate MAPK pathway activation, and *WT1* as well as *BAP1* function through transcriptional regulation (fig. S2C), we could not deduce any mechanistic explanation for the role of leucine zipper–like transcription regulator 1 (*LZTR1*) in enhanced CML cell survival from the existing literature (4, 5). To exclude cell line–specific effects, we confirmed that loss of

LZTR1 expression induced resistance to imatinib and rebastinib in other CML cell lines (fig. S4, A to C). Although we identified significant LZTR1 enrichment only in four of the genetic screens, KBM-7^{Cas9} sgLZTR1 cells exhibited various degrees of resistance against all tested BCR-ABL TKIs (fig. S3I). We used a CRISPR/Cas9-based domain scanning strategy to test whether both N-terminal Kelch domains and C-terminal Broad-Complex, Tramtrack, and Bric a brac (BTB) and partial BACK domains are essential for the drug-resistance phenotype (6-8). All protein domain-targeting sgRNAs showed efficient indel formation (fig. S3J) and induced resistant outgrowth of targeted cell populations exposed to rebastinib, indicating that the entire protein is functionally required (fig. S3K). To determine whether LZTR1 exerts its function only in a CML-specific context, we infected FLT3-ITD⁺ acute myeloid leukemia (AML) MV4-11^{Cas9} cells with LZTR1, targeting sgRNAs (fig. S4D). FLT3 inhibitor treatment led to an outgrowth of resistant cells, underlining a more general role for *LZTR1* in the drug response of hematopoietic cancers driven by different tyrosine kinases (fig. S4, E to G).

KBM-7^{Cas9} CML cells infected with distinct sgRNAs targeting LZTR1 displayed enhanced phosphorylation of MAPK kinase 1 (MEK1) and -2 and extracellular signal-regulated kinase 1 (ERK1) and -2, which is indicative of augmented MAPK pathway activation (Fig. 2A). By contrast, global tyrosine phosphorylation as well as phosphorylation of AKT (at S473 and T308), the protein kinase S6K1, ribosomal protein S6, and the direct BCR-ABL substrate signal transducer and activator of transcription 5 (STAT5) remained unchanged (fig. S4, J and K). Additional CML (K-562 and LAMA-84) and AML (MV4-11) cell lines had similarly enhanced MAPK pathway activation under normal growth conditions as well as, in the case of CML cells, upon increasing concentration of imatinib treatment (Fig. 2A and figs. S4, H and I, and S5, A to C). LZTR1 fulllength cDNA complementation in K-562^{Cas9} sgLZTR1 cells reverted both enhanced MEK and ERK phosphorylation as well as TKI resistance (Fig. 2, B and C). Treatment of K-562^{Cas9} sgLZTR1 cells with the clinically approved inhibitor of MEK1 and -2 trametinib reverted enhanced activation of ERK1 and -2 and pharmacologically counteracted the drug-resistance phenotype (Fig. 2, D and E). Furthermore, cDNA expression of constitutively active $Mek1^{D218, D222}$ (Mek1 DD) in K-562^{rtTA3} cells led to enhanced phosphorylation of ERK1 and -2 and reduced imatinib sensitivity (fig. S6A, and B). Activation of the MAPK pathway could also be inferred by the gene expression and transcription factor enrichment signature obtained with RNA sequencing experiments in KBM-7^{Cas9} sgLZTR1 compared with sgRen cells (fig. S5, D and E, and table S2). Altogether, the data established a causal role for enhanced MAPK pathway activation in the resistance of CML cells toward TKI therapy as elicited by loss of LZTR1 function.

Because BTB domain-containing proteins serve as adaptor proteins for the cullin 3 (CUL3) E3

ubiquitin ligase complex, enabling specific substrate recognition and ubiquitination (9), we tested whether loss of CUL3 expression could mimic the observed LZTR1 loss-of-function phenotype. K-562^{Cas9} sgCUL3 cells demonstrated enhanced MAPK pathway activation and, in contrast to sgLZTR1 cells, increased phosphorylation of AKT (fig. S4K). However, sgRNAs that target CUL3 had a pronounced antiproliferative effect both in KBM-7^{Cas9} and K-562^{Cas9} cells (fig. S6, C and D), providing a potential explanation why CUL3 was not detected in our genetic screens (fig. S2A).

In contrast to the CML cell lines, depletion of LZTR1 with CRISPR sgRNAs in HeLa, human embryonic kidney (HEK)–293T, or HAP1 cells did not increase MAPK pathway activation under

Α

С

comparable culture conditions (fig. S7, A and C). However, after serum stimulation of cells cultured without serum, HEK293T^{Cas9} sgLZTR1 cells showed a more pronounced activation of MEK and ERK than in control cells (fig. S7B). Similarly, in HAP1 cells, a non-hematopoietic derivative of the KBM-7 cell line (10), phorbol-12-myristat-13acetat (PMA) treatment led to enhanced MAPK pathway activation in the absence of LZTR1 compared with that in wild-type (WT) cells (fig. S7C). Whereas HAP1^{Cas9} sgCUL3 cells exhibited increased phosphorylation of ERK1, ERK2, and AKT (fig. S7F), loss of LZTR1 expression in HAP1^{Cas9} altered only the MAPK pathway as identified by means of pathway array-based assessment of kinase activation (fig. S7, D and E, and table S3).

Genetic studies have identified *LZTR1* mutations in glioblastoma (GBM) (*II*), schwannomatosis (SWNMT) (*8*), and Noonan syndrome (NS) (*5*), a developmental syndrome that is part of the larger group of RASopathies characterized by mutations in components of the RAS-MAPK pathway (*12*). Identification of *NF1* and *LZTR1* loss-of-function-induced MAPK pathway activation in our haploid resistance screens combined with human *LZTR1* mutations in NS indicated that *LZTR1* might directly regulate guanosine triphosphatases (GTPases) of the RAS family.

Drosophila wing vein formation and eye development serve as excellent in vivo readouts for RAS signaling (13–15). CG3711 encodes the Drosophila ortholog of mammalian LZTR1, which contains a specific N-terminal domain (amino

В

number of independent insertions per gene, and the color gradient depicts the FDR-adjusted *P* value of enrichment significance. (**C**) MCA-derived fold change of cell populations after imatinib treatment of KBM-7^{*Cas9*} CML cells transduced with sgRNAs targeting the "TOP6" genes or sg*Ren.*208 (targeting *Renilla luciferase*) as negative control. sgRNAinfected cell populations were mixed in a 1:1 ratio, treated with increasing drug concentrations, and analyzed by means of flow cytometry after 14 days. Data are shown as mean value \pm SD of at least two independent experiments ($n \ge 2$) performed in duplicates. sgRNAs are labeled by gene name followed by the genomic targeting sequence position numbered according to the sequence position on the corresponding mRNA.

acids 1 to 184) that is only found in *Drosophila*. This is followed by the highly conserved remaining part of the protein (54% sequence identity) (fig. S8, A to C). Systemic depletion of *CG3711* with RNA interference (RNAi) by using *act5C-Gal4* yielded viable flies; however, the majority of wings of these flies displayed wing vein defects characterized by extra veins and vein tissue (Fig. 3, A and B, and fig. S8D). This phenotype closely resembles a gain-of-function

Α

KBM-7^{Cas9}

increase of RAS-MAPK signaling (*15*) and could be rescued by a decrease in abundance of RAS via *dRas* (*Drosophila* Ras) heterozygosity (Fig. 3C). *Drosophila* R7 photoreceptor induction requires RAS function (*13, 14*). We used a mild dominant negative version, Ras^{V12C40}, which although locked in the active guanosine 5'-triphosphate (GTP)-bound state does not activate MAPK signaling (*16*). Ras^{V12C40} expression in the developing eyes (via the *sevenless/sev-Gal4* expression

K-562^{Cas9}

В

D

system) led to a frequent loss of the R7 photoreceptor (~30% of ommatidia display R7 loss, and some also lost other R-cells) (fig. S8, E and H). Because Ras^{V12C40} is constitutively active, it also causes defects in ommatidial rotation (*16, 17*), serving as internal control. When both *sev-Gal4*-driven *CG3711* RNAi and Ras^{V12C40} were expressed, the loss of R7 phenotype was almost completely suppressed (fig. S8, F and H). The ommatidial rotation defects were enhanced

Fig. 2. Loss of *LZTR1* enhances MAPK pathway activation.

(B) Immunoblot analysis of MEK and ERK phosphorylation as well as LZTR1 expression in sgRen.208expressing K-562^{Cas9} CML cells transduced with empty vector, and sgLZTR1.466expressing cells transduced with empty vector or LZTR1-cDNAcontaining murine stem cell virus (MSCV) retrovirus. Quantification of MEK and ERK phosphorylation is shown next to the corresponding immunoblots. (C) Competitive proliferation assay (MCA) of K-562^{Cas9} sgRen.208 cells transduced with empty vector and sgLZTR1.466 cells transduced with empty vector or LZTR1 cDNA after treatment with increasing concentrations of imatinib for 14 days. (D) Phosphorylation of MEK and ERK in K-562^{Cas9} cells expressing sgLZTR1.466 and treated with in-

creasing concentrations of trametinib for 3 hours. (**E**) Changes in cell populations measured with MCA of K-562^{Cas9} CML cells expressing sg*Ren.*208 or sg*LZTR1.*466 after 14 days of treatment with increasing concentrations of imatinib alone or in combination with trametinib. Immunoblot results in (A), (B), and (D) are representative of at least two independent biological experiments ($n \ge 2$). MCA data in (C) and (E) are shown as mean value \pm SD of at least two independent experiments ($n \ge 2$). Dimethyl sulfoxide (DMSO) treatment served as negative control.

rather than suppressed because these involve MAPK-independent RAS signaling (fig. S8F) (*16*). Expression of *CG3711* RNAi in the eye alone did not induce phenotypic changes (fig. S8, G and H). Thus, RAS is crucial for the phenotypes induced by depletion of *CG3711*.

To explore possible interactions of LZTR1 with RAS, we used a BirA* fusion protein-based proximity biotinylation-dependent (BioID) proteomic approach, which allows identification of weak interaction partners. We expressed KRAS4A, KRAS4B, NRAS, and HRAS as N-terminal FLAG-BirA* fusion proteins in K-562^{rtTA3} CML cells. This led to enhanced MEK and ERK activation, demonstrating that the BirA* tag does not generally interfere with RAS signaling (fig. S9A). We identified between 153 and 258 proteins in proximity of or interacting with human RAS proteins, among them several known interactors and pathway components (fig. S9, B to F, and table S4). A common set of 123 proteins repeatedly purified with all four RAS proteins, with gene ontology analysis showing a significant enrichment in components associated with plasma membrane and Golgi apparatus as well as the MAPK pathway (fig. S9, G and H). We identified LZTR1 among the most significant interactors of all four RAS proteins (fig. S9, B to F). Intersection of the 123 common interactors identified with BioID, with a fluorescence-activated cell sorting (FACS)-based haploid genetic pathway screen for the identification of gene knockout alleles that influence phosphorylation of ERK1 and -2 (18), revealed LZTR1 as the only common RAS interactor in our proteomic data with a negative regulatory function within the RAS-MAPK pathway (fig. S10A).

BioID proximity biotinylation-based and FLAG tag-based coimmunoprecipitation experiments confirmed the interaction of all four RAS proteins with endogenous LZTR1 (fig. S10, B and C). Only the four main RAS isoforms interacted specifically with LZTR1, whereas six related RAS family GTPases showed no interaction (fig. S11A). Nine other canonical positive RAS-MAPK pathway regulators also failed to interact with endogenous LZTR1 (fig. S11B). Immunoprecipitations with extracts derived from LZTR1 knockout cells confirmed the specificity of the interaction (fig. S11C). The C-terminal posttranslational acylations of KRAS proteins appeared to be required for the interaction with LZTR1 (Fig. 3D and fig. S11D). Thus, proper membrane-associated localization mediated by this region may be required for specific interaction with LZTR1.

Stably expressed full-length hemagglutinin (HA)-tagged LZTR1 protein showed a speckled and vesicular staining pattern in HeLa, HEK293T, and HAP1 cells, whereas all domain mutants had a homogenous cytoplasmic distribution (fig. S12, A to D). Full-length LZTR1 displayed an overlapping localization within speckled and vesicular compartments with transiently transfected V5-tagged CUL3 in HeLa cells (fig. S13A). The LZTR1-stained speckles further overlapped with the autophagosome marker LC3B fused to mCherry (fig. S13B), but we failed to detect LZTR1 lo-

calization with marker proteins of the Golgi. lysosome, peroxisome, or early and late endosome compartments (fig. S13C). Isoform-specific antibodies that recognize endogenous human RAS isoforms are not available (19). We therefore endogenously tagged KRAS (fig. S14A) and confirmed specificity of detection in immunofluorescence and immunoblotting by means of genetic inactivation of the tagged genomic allele (fig. S14, B to D). KRAS localized to a large number of small-punctate structures, likely membrane-containing small vesicles (Fig. 3E and fig. S14D). Inactivation of endogenous LZTR1 led to an increased RAS signal, particularly at the periphery of cells, at regions of cell-to-cell contacts (Fig. 3E and fig. S14D). This phenotype appeared to be dependent on the CUL3 E3 ligase complex because genetic inactivation of CUL3 led to similar phenotypic changes (Fig. 3E and fig. S14E).

We also assessed interaction of endogenously tagged KRAS with exogenous LZTR1 in HAP1 cells (fig. S15A). Exogenous LZTR1 localized to fewer, larger, and more oblong structures than did endogenous KRAS (fig. S15B). A fraction of the LZTR1-stained structures also contained KRAS. Treatment with the cullin neddylation inhibitor MLN4924 caused clustering of LZTR1containing structures that appeared to surround particles strongly stained with KRAS (fig. S15B, MLN4924 panel). Caution is required for the interpretation of these patterns because LZTR1 was overexpressed, and KRAS was at endogenous concentration. However, the images could represent a trapped proteostatic process that involves the two proteins.

We tested whether LZTR1 affected ubiquitination of RAS proteins by acting as a substrate adaptor for the CUL3 E3 ligase complex (11, 20). Ubiquitination of RAS proteins is known, but little is known of its consequences (21-25). Coexpression of HA-ubiquitin with either one of the four RAS isoforms alone only resulted in a basal state of ubiquitination, but addition of MYC-tagged CUL3 and V5-tagged LZTR1 led to increased ubiquitination of RAS proteins (fig. S16, A to D). LZTR1-deletion mutants that lack either one or both C-terminal BTB domains or the N-terminal Kelch domain failed to induce an equivalent degree of ubiquitination of KRAS4A (fig. S16A). KRAS4A required the presence of its C-terminal hypervariable region (HVR) and the farnesylated cysteine 186 for LZTR1-mediated ubiquitination (fig. S16E). LZTR1-induced ubiquitination was unchanged in cells treated with a proteasome inhibitor but could be blocked by cullin neddylation inhibition, which is consistent with the observed subcellular localization changes (fig. S16F). Specificity for LZTR1 in the process was further underscored by the failure of two prominent CUL3 adaptors, Kelch-like ECHassociated protein 1 (KEAP1) and Speckle-type POZ protein (SPOP), to cause a comparable ubiquitination (fig. S16G). We used HAP1 cells that bear endogenously tagged KRAS and tandem ubiquitin binding domain (TUBE) reagents to capture endogenously ubiquitinated proteins and evaluate the contribution of endogenous LZTR1 (26). In the absence of any stimulation, immunoprecipitation with TUBE purified several proteins that reacted with pan-ubiquitin antibodies (Fig. 3F, third from top, and fig. S16H). The same precipitates contained proteins that react with pan-RAS antibodies (Fig. 3F, second from top). Last, FLAG antibodies detected a protein not visible in the whole-cell extract (Fig. 3F, top, and fig. S16H). TUBE-mediated immunoprecipitation from corresponding cells in which LZTR1 had been genetically inactivated did not contain amounts of RAS detectable with these antibodies (Fig. 3F, top and second from top, and fig. S16H). The signal obtained with pan-ubiquitin antibodies was unchanged (Fig. 3F, third from top, and fig. S16H). Thus, human LZTR1 appears to mediate ubiquitination of endogenous human KRAS and possibly other RAS proteins.

If a main function of LZTR1 is to regulate RAS, then loss of RAS function should compensate for loss of LZTR1 activity, as suggested in the fruitfly epistatic analysis, representing an ideal experimental setup to assess the disease-associated LZTR1 mutations by their dependency on RAS activity. We confirmed that loss of LZTR1 function enhanced RAS activity in K-562 cells (fig. S17A). We then performed CRISPR/Cas9-based double-knockout MCA experiments (fig. S17, B to D). Single sgLZTR1 and sgLZTR1-sgRen doubleinfected cells were resistant to imatinib compared with control sgRen cells (fig. S17, E and F). sgRNAs that target KRAS abolished cellular outgrowth, whereas sgRNAs that target NRAS, HRAS, and RIT1 failed to do so (fig. S17, E and F). sgLZTR1sgKRAS cells had reduced MEK phosphorylation comparable with that of sgRen cells, whereas sgNRAS and sgHRAS cells maintained enhanced MAPK pathway activation (fig. S17G). KRAS inactivation led to a strong antiproliferative phenotype in KBM-7^{Cas9} cells and, to a lesser extent, K-562^{Cas9} cells (fig. S18, A and B), indicating that the selective requirement of KRAS in mediating LZTR1-induced enhanced MAPK pathway activation might represent a prerequisite of KRAS for BCR-ABL signaling in CML cells. We additionally used a fibronectin-fold-based monobody, NS1, which bears low nanomolar affinity for the dimerization interface of both KRAS and HRAS and is able to interfere with their signaling activities (27). Cells that stably express the NS1 monobody did not show increased activation of the MAPK pathway or drug resistance associated with loss of LZTR1 function (fig. S18, C and D).

More than 50 different mutations have been mapped to the human *LZTR1* gene in various diseases (fig. S19, A and B, and table S5) (*5*, *8*, *11*, 28–30). To establish a mechanistic link between mutations that affect human diseases and the biochemical processes described here, we focused on *LZTR1* missense mutations identified in GBM (*11*), NS (*5*), and SWNMT (*8*) (fig. S20B). Mutationbearing *LZTR1* cDNAs were tested for their ability to complement K-562 CML cells deficient in endogenous *LZTR1* (fig. S20A). In contrast to WT LZTR1, the disease-associated mutations

Fig. 3. LZTR1 modulates MAPK pathway activation through RAS regulation. <0.0001 (****). (**D**) FLAG immunoprecipitates (IP) and whole-cell extracts (WCE) from K-562'^{tTA3} cells expressing FLAG-BirA*–tagged GFP or KRAS4A WT, Δ HVR, C180S, or C186S after 48 hours of doxycycline treatment were immunoblotted for the indicated proteins. (**E**) Confocal microscopy of HAP1 WT cells and HAP1 cells with endogenously FLAG-tagged KRAS transduced with sg*Ren.*208, sg*LZTR1.*620, sg*LZTR1.*466, sg*CUL3.*852, or sg*CUL3.*1396 and stained with antibody to FLAG. Scale bars, 10 μ m. (**F**) TUBE-based purifications of ubiquitinated proteins and WCE from HAP1 WT and endogenously FLAG-tagged KRAS cells transduced with sg*Ren.*208 or sg*LZTR1.*466 were analyzed by means of immunoblotting with the indicated antibodies.

Fig. 4. *LZTR1* **disease missense mutations fail to rescue the loss-offunction phenotype.** (**A** to **C**) Immunoblotting for MEK and ERK phosphorylation as well as LZTR1 expression of K-562^{Cas9} sg*Ren.*208–expressing cells retrovirally transduced with empty vector, and sg*LZTR1.*466-expressing cells transduced with either empty vector, LZTR1 WT, or LZTR1 mutations identified in (A) GBM (blue), (B) NS (brown), or (C) SWNMT (orange). The LZTR1 G248R

failed to reduce MAPK pathway activation, despite being expressed at a comparable or higher amount (Fig. 4, A to C). Similarly, all missense mutations apart from the GBM-associated T288I and R810W failed to restore sensitivity to imatinib treatment (fig. S20, C to E). LZTR1 mutations within the Kelch domain partially retained their localization pattern in comparison with the WT protein, whereas mutations in the BTB/BACK domains mislocalized to the cytoplasm (fig. S21, A and B). In agreement, expression of LZTR1 Kelch domain mutations identified in GBM, NS, and SWNMT in K-562 WT cells had a resistance-mediating

effect in MCA assays in cells treated with imatinib, whereas BTB/BACK domain mutations did not (fig. S22, A to C). Furthermore, in contrast to the LZTR1 WT protein, the two mutants R198G and G248R identified in GBM and NS failed to induce a similar increase in ubiquitination on KRAS4A (fig. S22D). These findings provide functional evidence that human LZTR1 missense mutations identified in GBM, NS, and SWNMT represent loss-of-function toward ubiquitination and inhibition of RAS activity.

Together with the accompanying manuscript on the role of LZTR1 in diseases driven by the

dysregulation of RAS ubiquitination and signaling (*31*), our work illustrates the importance of an additional, underappreciated layer of RAS regulation (Fig. 4D).

ACKNOWLEDGMENTS

We are grateful to all members of the Superti-Furga laboratory for help, discussions, and advice; E. Girardi and E. Salzer for critically reading the manuscript: and P. Máiek for feedback on the bioinformatic analysis of BioID proteomic experiments. We thank the Biomedical Sequencing Facility for advice on Illumina sequencing and the Core Facility Imaging of the Medical University of Vienna for technical support. Funding: This work was supported by the Austrian Academy of Sciences, European Research Council (ERC) grants (i-FIVE 250179 and Game of Gates 695214) and Austrian Science Fund grant (EWE SEB F4711) to G.S.-F; European Molecular Biology Organization longterm fellowships to M.R. (ALTF 1346-2011) and G.I.V. (ALTF 1543-2012); an Austrian Science Fund grant (FWF SFB F4702) to R.K.; NIH grants R01 EY013256 and GM102811 to M.M.; and funding from the CGC.nl, KWF grant NKI 2015-7609, and ERC Starting Grant (ERC-2012-StG 309634) to T.R.B. Author contributions: J.W.B. and G.S.-F. conceived the study based on discussions with T.R.B.; J.W.B., F.K., and M.P. performed research; and G.M.C. and M.M. designed and performed Drosophila experiments. L.X.H., G.I.V., A.F., M.R., and G.E.W. generated reagents and provided scientific insight. F.S. analyzed haploid genetic screening data and created circos plots and the graphical display of insertion sites. V.S. performed RNA sequencing and enrichment analysis and compiled cBioPortal mutation data. K.P. and A.C.M. performed proteomic sample analysis. V.A.B. and T.R.B. provided reagents and gave experimental advice. R.K. supervised sequencing data analysis and gave experimental advice. J.W.B., G.M.C., F.K., G.I.V., L.X.H., F.S., M.M., and G.S.-F. analyzed and interpreted the data. J.W.B., M.M., and G.S.-F. wrote the paper. Competing interests: The authors declare no competing financial interest. T.R.B. is cofounder and SAB member of Haplogen GmbH and cofounder and managing director of Scenic Biotech. G.I.V. is cofounder and employee of Allcyte GmbH. G.S.-F. is cofounder and shareholder of Allcyte GmbH and Haplogen GmbH. Data and materials availability: Deep sequencing datasets have been deposited in the National Center for Biotechnology Information Sequence Read Archive under the accession no. SRP157890, and BioID mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium via the PRIDE partner repository under the accession no. PXD011280. The KBM-7 cell line is available from T.R.B. under a materials transfer agreement with the Netherlands Cancer Institute.

Science 362 (6419), 1171-1177. DOI: 10.1126/science.aap8210originally published online November 15, 2018

Regulation of RAS by ubiquitination The protein LZTR1 is mutated in human cancers and developmental diseases. Work from two groups now showed that mice haploinsufficient for LZTR1 recapitulated aspects of the human diseases. Work mice haploinsufficient for LZTR1 recapitulated aspects of the human disease Noonan syndrome. Their biochemical studies showed that LZTR1 associated with RAS. LZTR1 appears to function as an adaptor that promotes ubiquitination of RAS, thus inhibiting its signaling functions. Bigenzahn *et al.* found LZTR1 in a screen for proteins whose absence led to resistance to the tyrosine kinase inhibitors used to treat cancers caused by the BCR-ABL oncogene product. Their biochemical studies and genetic studies in fruitflies also showed that loss of LZTR1 led to increased activity of RAS and signaling through the mitogen-activated protein kinase pathway.
